CEOS

Campus Economy Operating System

Architecture Thesis · Phase 1 - FUNAAB Cluster Deployment

CONFIDENTIAL

The Campus Economy is Broken

The coordination failure no one has mapped

Nigeria has 200+ universities — each a closed economic cluster of 5,000–50,000 active agents transacting daily.

No discovery layer, no structured payment record, no map of capital flow exists for any of them.

This is a coordination failure, not a payments gap. The rails exist. The system does not.

We Are the Operating System

CEOS: The infrastructure layer above existing payment rails

CEOS sits above OPay, PalmPay, and Kuda — it does not replace them. It structures what they cannot.

Closed-loop Aggregator Wallet sub-ledger: instant, zero-fee, zero-network-failure transactions at point-of-sale.

Every transaction generates structured economic metadata — the foundation of a campus intelligence layer.

The Market Geometry

03

Vertical density vs. horizontal expansion

Total addressable market: 200+ federal and state universities — over 1M daily informal transactions.

Phase 1 thesis is vertical: dominate one cluster completely before horizontal replication.

Gross transaction volume per cluster (est.): ₦10M–₦25M per month at a 500-student, 15-vendor node.

The Product: Two Roles, One Ledger

Student Node · Vendor Hub · Internal Sub-Ledger

Students: frictionless vendor discovery and <500ms payment execution via QR scan.

Vendors: digital transaction history, payout visibility, and structured discoverability on campus.

Internal ledger: atomic sub-ledger transfers — no external NIBSS call required at point-of-sale.

The Aggregator Wallet Protocol

Why the UX works when everything else fails

Students pre-load a Campus Balance from their primary bank via a provisioned BaaS virtual account.

All campus transactions settle internally — removing NFC failure, network drop, and processing delay.

End-of-day batch settlement to vendor bank accounts via BaaS API (Bloc / Monnify / Kuda).

The Transaction Graph — The Real Asset

Metadata is the moat, not the middleware

Every transaction tagged: vendor type, location coordinates, timestamp, item-level context (JSONB).

Within 60 days: a behavioral map of campus economy — vendor density, student spend cycles, peak demand.

No bank, no fintech, no operator has ever produced this data asset for a Nigerian campus cluster.

GTM: Density Before Distribution

B2B2C through physical vendor lock-in

Acquire 15 vendors first — not 500 students. Vendors are distribution infrastructure, not customers.

Student adoption is a function of vendor density. Solve supply-side first; demand follows.

Liquidity incentive: platform-funded 5% subsidy on first-cycle transactions to accelerate habit formation.

Competitive Landscape

Why horizontal fintechs cannot replicate this

Flutterwave, Paystack, and OPay optimize for scale across open economies — not closure within micro-economies.

A campus-native coordination layer requires physical onboarding, QR infrastructure, and cluster-specific data.

The barrier to entry is not the technology stack — it is the willingness to go dense and physical before wide.

Traction & Phase 1 Milestones

FUNAAB Cluster Deployment Schedule

Week 1–2: 15 vendors manually onboarded, QR standees installed, backend sub-ledger live.

Week 3–6: 500 students acquired through hostel-adjacent activation and 5% incentive campaign.

Week 7–12: Subsidy removed; retention measured against raw UX. First economic map output produced.

Let’s Build.

FUNAAB Rollout + Distribution Architecture

IMMEDIATE EXECUTION

Vendor onboarding is staged. QR infrastructure is ready. Sub-ledger activation begins this cycle. The first node goes live now.

CLOSED-LOOP MAPPING

Within 60 days of activation, FUNAAB generates the first structured campus transaction graph in Nigeria. Vendor density, spend cycles, peak demand curves.

DISTRIBUTION ARCHITECTURE

The model scales through campus network operators. If you run distribution on any cluster, let’s build this together.
